Preferred mutations of the invention:																															

(57) **Abstract:** The present invention provides a polypeptide comprising (i) a leader sequence, the leader sequence comprising (a) secretion pre sequence, and (b) the following motif: -X<sub>1</sub>-X<sub>2</sub>-X<sub>3</sub>-X<sub>4</sub>-X<sub>5</sub>- where X<sub>1</sub> is phenylalanine, tryptophan, or tyrosine, X<sub>2</sub> is isoleucine, leucine, valine, alanine or methionine, X<sub>3</sub> is leucine, valine, alanine or methionine, X<sub>4</sub> is serine or threonine and X<sub>5</sub> is isoleucine, valine, alanine or methionine; and (ii) a desired protein heterologous to the leader sequence. A polypeptide of the invention may additionally comprise, as part of the leader sequence, a secretion pro sequence. The invention also provides a polynucleotide comprising a sequence that encodes a polypeptide of the invention and a cell, preferably a yeast cell, comprising said polynucleotide.

## GENE AND POLYPEPTIDE SEQUENCES

The present invention relates to polypeptide and polynucleotide sequences for secreting proteins from host cells.

5

Numerous natural or artificial polypeptide signal sequences (also called secretion pre regions) have been used or developed for secreting desired peptides, polypeptides and proteins (these terms are used interchangeably from hereon in) from host cells. The signal sequence directs the nascent  
10 protein towards the machinery of the cell that exports proteins from the cell into the surrounding medium or, in some cases, into the periplasmic space. The signal sequence is usually, although not necessarily, located at the N-terminus of the primary translation product and is generally, although not necessarily, cleaved off the desired protein during the secretion process, to  
15 yield the "mature" protein.

In the case of some desired proteins the entity that is initially secreted, after the removal of the signal sequence, includes additional amino acids at its N-terminus called a "pro" sequence, the intermediate entity being called a  
20 "pro-protein". These pro sequences may assist the final protein to fold and become functional, and are usually then cleaved off. In other instances, the pro region simply provides a cleavage site for an enzyme to cleave off the pre-pro region and is not known to have another function.

25 The pro sequence can be removed either during the secretion of the desired protein from the cell or after export from the cell into the surrounding medium or periplasmic space.

Polypeptide sequences which direct the secretion of proteins, whether they  
30 resemble signal (i.e. pre) sequences or pre-pro secretion sequences, are

sometimes also referred to as leader sequences. The secretion of proteins is a dynamic process involving translation, translocation and post-translational processing, and one or more of these steps may not necessarily be completed before another is either initiated or completed.

5

For production of proteins in eukaryotic species such as the yeasts *Saccharomyces cerevisiae* and *Pichia pastoris*, known leader sequences include those from the *S. cerevisiae* acid phosphatase protein (Pho5p) (see EP 366 400), the invertase protein (Suc2p) (see Smith *et al.* (1985) *Science*,  
10 229, 1219-1224) and heat-shock protein-150 (Hsp150p) (see WO 95/33833). Additionally, leader sequences from the *S. cerevisiae* mating factor alpha-1 protein (MF $\alpha$ -1) and from the human lysozyme and human serum albumin (HSA) protein have been used, the latter having been used especially, although not exclusively, for secreting human albumin. WO  
15 90/01063 discloses a fusion of the MF $\alpha$ -1 and HSA leader sequences, which advantageously reduces the production of a contaminating fragment of human albumin relative to the use of the MF $\alpha$ -1 leader sequence.

Unexpectedly, we have found that the yield of secreted protein can be  
20 increased by the introduction of an amino acid sequence motif, preferably by modification of leader sequences. The modifications are effective whether made to the complete native albumin leader sequence, variants thereof, or to other leader sequences that employ the relevant part of the human albumin leader sequence, such as the fusion of MF $\alpha$ -1 and HSA  
25 leader sequences as disclosed in WO 90/01063. In the latter case, if albumin is the protein secreted, the albumin thus produced retains the advantageous feature of reduced contaminating fragment, whilst still increasing the yield.

Although conservative modifications of the fused leader sequence of WO 90/01063 were disclosed in general terms in WO 90/01063 (for example, see page 8 of WO 90/01063), this resulted in a class of some  $8 \times 10^{12}$  polypeptides being defined. Polynucleotide coding sequences were set out  
5 for the exemplified leader sequence, according to the degeneracy of the genetic code. This also represents a large number of possibilities. There is no appreciation in WO 90/01063 that the specific class of modified leader sequences provided by the present invention would have advantageous properties for expression of secreted protein.

10

In a first aspect of the present invention there is provided a polypeptide comprising (i) a leader sequence, the leader sequence comprising (a) a secretion pre sequence and (b) the following motif:

15

20

where  $X_1$  is phenylalanine, tryptophan, or tyrosine,  $X_2$  is isoleucine, leucine, valine, alanine or methionine,  $X_3$  is leucine, valine, alanine or methionine,  $X_4$  is serine or threonine and  $X_5$  is isoleucine, valine, alanine or methionine;  
and (ii) a desired protein, heterologous to the leader sequence.

In other words, the polypeptide includes a sequence according to SEQ ID NO 1 –

25

N-(Phe/Trp/Tyr)-(Ile/Leu/Val/Ala/Met)-(Leu/Val/Ala/Met)-  
(Ser/Thr)-(Ile/Val/Ala/Met)-C

**SEQ ID No 1**

5 N-Phe-(Ile/Leu/Val/Ala/Met)-(Leu/Val/Ala/Met)-(Ser/Thr)-  
(Ile/Val/Ala/Met)-C

In another preferred embodiment of the first aspect of the present invention,  
10 X<sub>2</sub> is isoleucine. Thus another preferred polypeptide includes the sequence  
of SEQ ID NO 3 -

N-(Phe/Trp/Tyr)-Ile-(Leu/Val/Ala/Met)-(Ser/Thr)-  
(Ile/Val/Ala/Met)-C

In another preferred embodiment of the first aspect of the present invention, X<sub>3</sub> is valine. Thus another preferred polypeptide includes the sequence of SEQ ID NO 4 -

N-(Phe/Trp/Tyr)-(Ile/Leu/Val/Ala/Met)-Val-(Ser/Thr)-  
(Ile/Val/Ala/Met)-C

**SEO ID No 4**

In another preferred polypeptide X<sub>4</sub> is serine and so includes the sequence of SEQ ID NO 5 -

N-(Phe/Trp/Tyr)-(Ile/Leu/Val/Ala/Met)-(Leu/Val/Ala/Met)-Ser-  
(Ile/Val/Ala/Met)-C

**SEQ ID No 5**

In another preferred embodiment of the first aspect of the present invention, X<sub>4</sub> is threonine. Thus another preferred polypeptide includes the sequence of SEQ ID NO 29 -

5

N-(Phe/Trp/Tyr)-(Ile/Leu/Val/Ala/Met)-(Leu/Val/Ala/Met)-Thr-  
(Ile/Val/Ala/Met)-C

SEQ ID No 29

10 In another preferred embodiment of the first aspect of the present invention, X<sub>5</sub> is isoleucine. Thus another preferred polypeptide includes the sequence of SEQ ID NO 6 -

15 N-(Phe/Trp/Tyr)-(Ile/Leu/Val/Ala/Met)-(Leu/Val/Ala/Met)-  
(Ser/Thr)-Ile-C

SEQ ID No 6

20 More preferably at least 2, even more preferably at least 3, yet more preferably at least 4 of X<sub>1</sub>, X<sub>2</sub>, X<sub>3</sub>, X<sub>4</sub> and X<sub>5</sub> are as defined in the preferred embodiments above.

25 The motif may be inserted into the leader sequence (i.e. as an addition), or can be included as a substitute for 1, 2, 3, 4, 5 or more contiguous amino acids within the leader sequence.

30 In one preferred embodiment, the motif is included in the leader sequence as a substitution for naturally occurring amino acids. In other words, the amino acids of the motif are included in the place of five contiguous amino acids that were, or would have been, present in the leader sequence prior to

its optimisation according to the present invention. The reader will appreciate that the phrase "naturally occurring" when used in this context, is not intended to limit the invention to the optimisation of naturally occurring leader sequences. On the contrary, this invention is also applicable to the  
5 optimisation of artificial leader sequences, such as the HSA/MF $\alpha$ -1 leader sequence fusion the optimisation of which is exemplified herein.

It is preferable that, where the motif is included in the leader sequence as a substitution then X<sub>4</sub> is the naturally occurring amino acid, or a variant  
10 thereof. In other words, preferably only X<sub>1</sub>, X<sub>2</sub>, X<sub>3</sub> and X<sub>5</sub> are substituted, whilst X<sub>4</sub> is maintained unchanged, or simply changed to a variant, preferably as a conservative substitution as defined below, of the natural amino acid at that position.

15 In a particularly preferred embodiment of the first aspect of the present invention, X<sub>1</sub> is phenylalanine, X<sub>2</sub> is isoleucine, X<sub>3</sub> is valine, X<sub>4</sub> is serine and X<sub>5</sub> is isoleucine. Thus in a particularly preferred embodiment of the first aspect of the invention, there is provided a polypeptide which includes the sequence of SEQ ID No 7 -

20

N-Phe-Ile-Val-Ser-Ile-C

**SEQ ID No 7**

25 In the above schemes, "N" and "C" denote the orientation of the polypeptide sequence, and are not intended to be limited in their interpretation to the actual termini; in other words, the polypeptide sequence may be joined (e.g. fused, conjugated or ligated), to one or more other polypeptide sequences at either the N-, or C- ends, or most usually at both  
30 ends.

- A polypeptide according to the first aspect of the invention comprises the sequence of a mature desired protein, heterologous to the leader sequence. A mature desired protein sequence is the primary amino acid sequence that will be present in the expression product following post-translational processing by the expression system in which the polypeptide of the invention is expressed. The desired protein is preferably suitable for secretion from a cell in which the polypeptide of the invention is expressed.
- 10 The desired protein is heterologous to the leader sequence. In other words, the polypeptide of the first aspect of the present invention does not include naturally occurring proteins that have, in their leader sequences, the motif -X<sub>1</sub>-X<sub>2</sub>-X<sub>3</sub>-X<sub>4</sub>-X<sub>5</sub>- as defined above. In a preferred embodiment, the polypeptide of the first aspect of the present invention does not include any
- 15 naturally occurring protein that has the motif -X<sub>1</sub>-X<sub>2</sub>-X<sub>3</sub>-X<sub>4</sub>-X<sub>5</sub>- as defined above at any position. In this context, the term "naturally occurring" refers to proteins encoded by naturally occurring organisms that have not been modified by recombinant technology, site-directed mutagenesis or equivalent artificial techniques that requires human intervention.
- 20
- The desired protein may comprise any sequence, be it natural protein (including a zymogen), polypeptide or peptide, or a variant, or a fragment (which may, for example, be a domain) of a natural protein, polypeptide or peptide; or a totally synthetic protein, polypeptide or peptide; or a single or
- 25 multiple fusion of different proteins, polypeptides or peptides (natural or synthetic). Such proteins can be taken, but not exclusively, from the lists provided in WO 01/79258, WO 01/79271, WO 01/79442, WO 01/79443, WO 01/79444 and WO 01/79480, or a variant or fragment thereof; the disclosures of which are incorporated herein by reference. Although these
- 30 patent applications present the list of proteins in the context of fusion

partners for albumin, the present invention is not so limited and, for the purposes of the present invention, any of the proteins listed therein may be presented alone or as fusion partners for albumin, the Fc region of immunoglobulin, transferrin or any other protein as a desired polypeptide.

5

Preferred examples of a desired protein for expression by the present invention includes albumin, transferrin, lactoferrin, endostatin, angiostatin, collagens, immunoglobulins, Fab' fragments, F(ab')<sub>2</sub>, ScAb, ScFv, interferons, IL10, IL11, IL2, interferon  $\alpha$  species and sub-species, interferon  $\beta$  species and sub-species, interferon  $\gamma$  species and sub-species, IL1-receptor antagonist, EPO, TPO, prosaptide, cyanovirin-N, 5-helix, T20 peptide, T1249 peptide, HIV gp41, HIV gp120, fibrinogen, urokinase, prourokinase, tPA (tissue plasminogen activator), hirudin, platelet derived growth factor, parathyroid hormone, proinsulin, insulin, insulin-like growth factor, calcitonin, growth hormone, transforming growth factor  $\beta$ , tumour necrosis factor, G-CSF, GM-CSF, M-CSF, coagulation factors in both pre and active forms, including but not limited to plasminogen, fibrinogen, thrombin, pre-thrombin, pro-thrombin, von Willebrand's factor,  $\alpha_1$ -antitrypsin, plasminogen activators, Factor VII, Factor VIII, Factor IX, Factor X and Factor XIII, nerve growth factor, LACI (lipoprotein associated coagulation inhibitor, also known as tissue factor pathway inhibitor or extrinsic pathway inhibitor), platelet-derived endothelial cell growth factor (PD-ECGF), glucose oxidase, serum cholinesterase, aprotinin, amyloid precursor, inter-alpha trypsin inhibitor, antithrombin III, apo-lipoprotein species, Protein C, Protein S, a variant or fragment of any of the above.

A "variant", in the context of a desired protein, refers to a protein wherein at one or more positions there have been amino acid insertions, deletions, or substitutions, either conservative or non-conservative, provided that such changes result in a protein whose basic properties, for example enzymatic

activity or receptor binding (type of and specific activity), thermostability, activity in a certain pH-range (pH-stability) have not significantly been changed. "Significantly" in this context means that one skilled in the art would say that the properties of the variant may still be different but would not be  
5 unobvious over the ones of the original protein.

By "conservative substitutions" is intended combinations such as Val, Ile, Leu, Ala, Met; Asp, Glu; Asn, Gln; Ser, Thr, Gly, Ala; Lys, Arg, His; and Phe, Tyr, Trp. Preferred conservative substitutions include Gly, Ala; Val, Ile,  
10 Leu; Asp, Glu; Asn, Gln; Ser, Thr; Lys, Arg; and Phe, Tyr.

A "variant" typically has at least 25%, at least 50%, at least 60% or at least 70%, preferably at least 80%, more preferably at least 90%, even more preferably at least 95%, yet more preferably at least 99%, most preferably at  
15 least 99.5% sequence identity to the polypeptide from which it is derived.

The percent sequence identity between two polypeptides may be determined using suitable computer programs, for example the GAP program of the University of Wisconsin Genetic Computing Group and it will be  
20 appreciated that percent identity is calculated in relation to polypeptides whose sequence has been aligned optimally.

The alignment may alternatively be carried out using the Clustal W program (Thompson *et al.*, (1994) *Nucleic Acids Res.*, 22(22), 4673-80). The  
25 parameters used may be as follows:

- Fast pairwise alignment parameters: K-tuple(word) size; 1, window size; 5, gap penalty; 3, number of top diagonals; 5. Scoring method: x percent.
- Multiple alignment parameters: gap open penalty; 10, gap extension  
30 penalty; 0.05.

- Scoring matrix: BLOSUM.

Such variants may be natural or made using the methods of protein engineering and site-directed mutagenesis as are well known in the art.

5

A "fragment", in the context of a desired proteins, refers to a protein wherein at one or more positions there have been deletions. Thus the fragment may comprise at most 5, 10, 20, 30, 40 or 50% of the complete sequence of the full mature polypeptide. Typically a fragment comprises up to 60%, more typically up to 70%, preferably up to 80%, more preferably up to 90%, even more preferably up to 95%, yet more preferably up to 99% of the complete sequence of the full desired protein. Particularly preferred fragments of a desired protein comprise one or more whole domains of the desired protein. For example, the desired protein may be albumin. Albumin has three domains. A particularly preferred fragment of albumin may contain one or two domains and will thus typically comprise at least 33% or at least 66% of the complete sequence of albumin.

Albumin and transferrin, or variants or fragments thereof, are particularly preferred as a desired protein, especially when they are of human origin, i.e. they have same sequence as that found in the naturally produced human protein.

The term "human albumin" is used herein to denote material which is indistinguishable from human serum albumin or which is a variant or fragment thereof. By "variant" we include insertions, deletions and substitutions, either conservative or non-conservative, where such changes do not substantially alter the oncotic, useful ligand-binding or immunogenic properties of albumin. For example we include naturally-occurring polymorphic variants of human albumin or human albumin analogues

disclosed in EP-A-322 094. Generally, variants or fragments of human albumin will have at least 10% (preferably at least 50%, 80%, 90% or 95%) of human serum albumin's ligand binding activity (for example bilirubin-binding) and at least 50% (preferably at least 80%, 90% or 95%) of human serum albumin's oncotic activity, weight for weight. Oncotic activity, also known as colloid osmotic pressure, of albumin, albumin variants or fragments of albumin may be determined by the method described by Hoefs, J.C. (1992) *Hepatology* 16:396-403. Bilirubin binding may be measured by fluorescence enhancement at 527 nm relative to HSA. Bilirubin (1.0mg) is dissolved in 50 $\mu$ L of 1M NaOH and diluted to 1.0mL with demineralised water. The bilirubin stock is diluted in 100mM Tris-HCl pH8.5, 1mM EDTA to give 0.6nmol of bilirubin mL<sup>-1</sup> in a fluorometer cuvette. Fluorescence is measured by excitation at 448nm and emission at 527nm (10nm slit widths) during titration with HSA over a range of HSA:bilirubin ratios from 0 to 5 mol:mol.

In a preferred embodiment, the desired protein may be transferrin. This includes members of the transferrin family (Testa, *Proteins of iron metabolism*, CRC Press, 2002; Harris & Aisen, *Iron carriers and iron proteins*, Vol. 5, Physical Bioinorganic Chemistry, VCH, 1991) and their derivatives, such as transferrin, mutant transferrins (Mason *et al*, 1993, *Biochemistry*, 32, 5472; Mason *et al*, 1998, *Biochem. J.*, 330(1), 35), truncated transferrins, transferrin lobes (Mason *et al*, 1996, *Protein Expr. Purif.*, 8, 119; Mason *et al*, 1991, *Protein Expr. Purif.*, 2, 214), lactoferrin, mutant lactoferrins, truncated lactoferrins, lactoferrin lobes or fusions of any of the above to other peptides, polypeptides or proteins (Shin *et al*, 1995, *Proc. Natl. Acad. Sci. USA*, 92, 2820; Ali *et al*, 1999, *J. Biol. Chem.*, 274, 24066; Mason *et al*, 2002, *Biochemistry*, 41, 9448). The transferrin may be human transferrin.

The term "human transferrin" is used herein to denote material which is indistinguishable from transferrin derived from a human or which is a variant or fragment thereof. A "variant" includes insertions, deletions and substitutions, either conservative or non-conservative, where such changes do not substantially alter the useful ligand-binding or immunogenic properties of transferrin. For example we include naturally-occurring polymorphic variants of human transferrin or human transferrin analogues. Generally, variants or fragments of human transferrin will have at least 50% (preferably at least 80%, 90% or 95%) of human transferrin's ligand binding activity (for example iron-binding), weight for weight. The iron binding activity of transferrin or a test sample can be determined spectrophotometrically by 470nm:280nm absorbance ratios for the proteins in their iron-free and fully iron-loaded states. Reagents should be iron-free unless stated otherwise. Iron can be removed from transferrin or the test sample by dialysis against 0.1M citrate, 0.1M acetate, 10mM EDTA pH4.5. Protein should be at approximately 20mg/mL in 100mM HEPES, 10mM NaHCO<sub>3</sub> pH8.0. Measure the 470nm:280nm absorbance ratio of apo-transferrin (Calbiochem, CN Biosciences, Nottingham, UK) diluted in water so that absorbance at 280nm can be accurately determined spectrophotometrically (0% iron binding). Prepare 20mM iron-nitrilotriacetate (FeNTA) solution by dissolving 191mg nitrotriactic acid in 2mL 1M NaOH, then add 2mL 0.5M ferric chloride. Dilute to 50mL with deionised water. Fully load apo-transferrin with iron (100% iron binding) by adding a sufficient excess of freshly prepared 20mM FeNTA, then dialyse the holo-transferrin preparation completely against 100mM HEPES, 10mM NaHCO<sub>3</sub> pH8.0 to remove remaining FeNTA before measuring the absorbance ratio at 470nm:280nm. Repeat the procedure using test sample, which should initially be free from iron, and compare final ratios to the control.

Additionally, single or multiple heterologous fusions of any of the above; or single or multiple heterologous fusions to albumin, transferrin or immunoglobins or a variant or fragment of any of these may be used. Such fusions include albumin N-terminal fusions, albumin C-terminal fusions and co-N-terminal and C-terminal albumin fusions as exemplified by WO 01/79271, and transferrin N-terminal fusions, transferrin C-terminal fusions, and co-N-terminal and C-terminal transferrin fusions.

In a preferred embodiment, a polypeptide according to a first aspect of the invention comprises a secretion pre sequence that includes at least a part of the  $X_1$ - $X_5$  pentapeptide motif as defined above. In other words, the region of the leader sequence that acts to effect secretion of the mature desired polypeptide contains, 1, 2, 3, 4, or 5 of the amino acids of the  $X_1$ - $X_5$  pentapeptide motif. Where the secretion pre sequence region contains less than 5 amino acids of the  $X_1$ - $X_5$  pentapeptide motif, those amino acids of the motif that are contained in the pre sequence are located at one of the borders of the pre sequence region, such that they are adjacent to the remaining amino acids of the  $X_1$ - $X_5$  pentapeptide motif.

In a more preferred embodiment a polypeptide according to a first aspect of the present invention comprises a leader sequence characterised in that it includes a secretion pre sequence that includes the motif as defined above by the first aspect of the present invention. The leader sequence is usually, although not necessarily, located at the N-terminus of the primary translation product and is generally, although not necessarily, cleaved off the protein during the secretion process, to yield the mature "desired" protein.

A secretion leader sequence is usually, although not necessarily, an N-terminal sequence of amino acids that causes the polypeptide of which it

forms part to be secreted from a host cell in which it is produced. Secretion is defined by the co-translational or post-translation translocation of a protein from the cytoplasmic compartment across a phospholipid bilayer, typically, but not exclusively the endoplasmic reticulum of eukaryotic organisms or the plasma membrane of prokaryotic organisms. The secreted protein may be retained within the confines of the cell (typically, but not exclusively, within the endoplasmic reticulum, Golgi apparatus, vacuole, lysosome or periplasmic space) or it may be secreted from the cell into the culture medium. A sequence acts as a secretion leader sequence if, in comparison to an equivalent polypeptide without the secretion pre sequence, it causes more of that polypeptide to be secreted from the host cell in which it is produced. Generally speaking, a polypeptide with a leader sequence will be secreted whereas a polypeptide without a leader sequence will not. However, the present invention contemplates circumstances wherein different leader sequences will have different levels of efficiency. Thus a leader sequence may cause at least 10%, 20%, 30 or 40% or 50%, typically at least 60% or 70%, preferably at least 80%, more preferably at least 90%, even more preferably at least 95%, yet more preferably at least 98%, most preferably at least 99% of the mature protein produced by the cell to be secreted from the cell. Secretion of a mature polypeptide from a cell can be determined, for example, by providing a host cell with appropriate DNA constructs and measuring the amount of the mature protein (for example, human albumin) that is secreted, compared with any mature protein that is produced intracellularly.

25

A preferred secretion leader sequence will provide for the above mentioned levels of secretion when the host cell is a yeast cell (eg. *Saccharomyces cerevisiae* or *Pichia pastoris*). Secretion of a mature polypeptide from a yeast host cell can be determined, for example, by methods such as those set out in the examples below.

30

Accordingly, secretion can be measured by comparing the level of secretion of a protein comprising a test leader sequence to the level of secretion of a protein comprising a control leader sequence. In order to determine whether a given sequence (the "test sequence") is able to achieve a given level of secretion, a first protocol may be used in which a 'starter' plasmid, typically a yeast disintegration vector of the type described in EP 0 286 422, having the *LEU2* gene and a polynucleotide encoding rHA with a modified leader sequence as defined by SEQ ID NO:26 operably linked to functional yeast regulatory regions, such as a PRB1 promoter and an ADH1 terminator as described below, is modified to include a polynucleotide sequence that encodes the test sequence in place of an equivalent region of the leader sequence, thereby to provide a test plasmid. As a first control, the unmodified 'starter' plasmid encoding the leader sequence described in WO 90/01063 is used. *Saccharomyces cerevisiae* strain AH22 *cir*<sup>0</sup> (Hinnen *et al.*, 1978, *Proc. Natl. Acad. Sci. USA*, 75(4), 1929-33; Mead *et al.*, 1986, *Mol. Gen. Genet.*, 205, 417), His4 reverted, is used as a test host. A HIS4 revertant (i.e. His+) of AH22 (*leu2*, *his4*, *can1*) can be obtained by culturing sufficient AH22 cells on BMMD agar, supplemented with 0.002% (w/v) leucine, until colonies appear. The colonies are tested to confirm that that are Leu- and His+ ( i.e. AH22 His+ (*leu2*, *can1*)) by plating onto BMMD agar, supplemented with 0.002% (w/v) leucine (plate 1), BMMD agar, supplemented with 0.002% (w/v) leucine and, supplemented with 0.002% (w/v) histidine (plate 2), and BMMD agar (plate 3). AH22 His+ (*leu2*, *can1*) isolates will grow on plate 1 and plate 2, but will not grow on plate 3. The test host is transformed to leucine prototrophy with the test and control plasmids. Transformants are patched out onto Buffered Minimal Medium (BMM, described by Kerry-Williams, S.M. *et al.* (1998) *Yeast* 14, 161-169) containing 2% (w/v) glucose (BMMD) and incubated at 30°C until grown sufficiently for further analysis. Transformants are cultivated in high cell

density fermentation according to a fill & draw procedure, in a medium and using control parameters as described for the fed-batch procedure in WO 96/37515: upon completion of the feed phase of the fed-batch culture procedure, 90% of the culture volume is removed from the fermenter vessel.

5 Batch medium is added to the remaining 10% volume of the culture (maintaining pH control) prior to the initiation of feed addition, using the medium and control parameters described in WO 96/37515. The procedure of fill & draw can be repeated for an unlimited number of cycles. The human albumin productivity ( $Y_{P/S}$ ) of the transformants containing test and

10 control plasmids are assessed by scanning densitometry of SDS-PAGE of cell free whole culture.  $Y_{P/S}$  represents the ratio of human albumin protein (mg) per gram of sucrose added to the culture during fermentation.

A leader sequence according to the present invention may obtain a level of

15 secretion, as determined by  $Y_{P/S}$  as measured by the above first protocol, that is at least 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 100%, 110%, 120%, 130%, 140%, 150%, 160%, 170%, 180%, 190%, 200%, 210%, 220%, 230%, 240%, 250%, 260%, 270%, 280%, 290%, 300%, 310%, 320%, 330%, 340%, 350%, 360%, 370%, 380%, 390%, 400%, 410%, 420%, 430%, 440%,

20 450%, 460%, 470%, 480%, 490% or 500% higher than the level of secretion obtained by the first control when the test and first control transformants are cultured for comparable lengths of time with comparable fermenter configurations. Thus a leader sequence according to the present invention may demonstrate a level of secretion that is up to 400%, 450%, 500%, 550%,

25 600%, 650%, 700%, 750%, or more higher than the first control. It is particularly preferred that a leader sequence according to the present invention can obtain a level of secretion at least 400%, such as 408%, or at least 440%, such as 442%, higher than the level of secretion obtained by the first control.

As an alternative to the first protocol, a second protocol may be used to determine whether a given sequence (the "test sequence") is able to achieve a given level of secretion. The second protocol is essentially the same as the first protocol. However, the second protocol utilises a 'starter' plasmid as defined above with the exception that, in place of SEQ ID NO:26 the plasmid has the polynucleotide sequence defined by SEQ ID NO:22, which also encodes a leader sequence having the amino acid sequence described in WO 90/01063 linked to a polynucleotide encoding rHA (the "second starter" plasmid). A test plasmid is produced by modifying the second starter plasmid to include a polynucleotide sequence that encodes the test sequence in place of an equivalent region of the leader sequence of the second starter plasmid. As a second control, the unmodified second starter plasmid is used. Transformants comprising the test and second control plasmids are prepared as described above in the first protocol and cultivated in a high cell density fermentation according to a fed-batch procedure in a medium and using control parameters as described in WO 96/37515.  $Y_{P/S}$  is assessed as described above.

A leader sequence according to the present invention may obtain a level of secretion, as determined by  $Y_{P/S}$  as measured by the above second protocol, that is at least 1%, 2%, 3%, 4%, 5%, 6%, 7%, 8%, 9%, 10%, 11%, 12%, 13%, 14%, 15%, 16%, 17%, 18%, 19% or 20% higher than the level of secretion obtained by the second control when the test and second control transformants are cultured for comparable lengths of time with comparable fermenter configurations. Thus a leader sequence according to the present invention may demonstrate a level of secretion that is up to 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 100% or more higher than the second control. It is particularly preferred that a leader sequence according to the present invention can obtain a level of secretion at least 5%, such as 6%, or at least 10%, such as

12%, 13%, 14%, 15% or 16% higher than the level of secretion obtained by the second control.

In one embodiment, a leader sequence according to the present invention will obtain a level of secretion as defined above in respect of the first protocol. In another embodiment, a leader sequence according to the present invention will obtain a level of secretion as defined above in respect of the second protocol. In a particularly preferred embodiment, a leader sequence according to the present invention will obtain a level of secretion as defined above in respect of both the first and second protocols.

Solubilised proteins from the cell biomass and secreted proteins in the culture supernatant can be analysed by:

1. Gel permeation high pressure liquid chromatography.
2. Densitometry of SDS-PAGE
3. Rocket immunoelectrophoresis

The amount of the desired protein, secreted and intracellular, can be quantified relative to a standard curve of the desired protein and normalised to the amount of biomass as known by those skilled in the art.

Usually it is preferable if the leader sequence is derived from the immature version of the mature protein to which it is, or is intended to be, attached. Thus, for example, where the mature protein is albumin, it is preferred to use sequences comprising the naturally occurring albumin secretion pre sequence, or pro sequence or pre-pro sequence. However, the leader sequence may alternatively be derived from a source other than that of the mature protein.

Thus in one preferred embodiment, the leader sequence of a polypeptide of the first aspect of the present invention comprises a secretion pre sequence derived from an albumin secretion pre sequence, or variant thereof.

- 5 A "variant" of an albumin pre sequence, as used above, refers to an albumin pre sequence wherein at one or more positions, other than at those defined by  $X_1$ ,  $X_2$ ,  $X_3$ ,  $X_4$  or  $X_5$  above, there have been amino acid insertions, deletions, or substitutions, either conservative (as described above) or non-conservative, provided that such changes still allow the peptide to act as a pre sequence.

10

- Preferably, a "variant" of an albumin pre sequence has, other than the residues defined as  $X_1$ - $X_5$  above, at least 2, at least 3 or at least 4, preferably at least 5, more preferably at least 6, even more preferably at least 7, yet more preferably at least 8, most preferably at least 9 identical amino acids to  
15 a naturally occurring albumin pre sequence, most preferably the albumin pre sequence of Figure 1.

- Even more preferably, where the secretion pre sequence is derived from an albumin secretion pre sequence, a polypeptide according to the first aspect  
20 of the present invention has  $X_1$ ,  $X_2$ ,  $X_3$ ,  $X_4$  and  $X_5$  at positions -20, -19, -18, -17 and -16, respectively, in place of the naturally occurring amino acids at those positions, wherein the numbering is such that the -1 residue is the C-terminal amino acid of the native albumin secretion pro sequence and where  $X_1$ ,  $X_2$ ,  $X_3$ ,  $X_4$  and  $X_5$  are amino acids as defined above

25

For example, when the above mentioned numbering is applied to the sequence of the human albumin secretion pre sequence (as disclosed, for example in WO 90/01063), the following is obtained:

N	-	Met	Lys	Trp	Val	Ser	Phe	Ile	Ser	Leu	Leu
		-24	-23	-22	-21	-20	-19	-18	-17	-16	-15
		Phe	Leu	Phe	Ser	Ser	Ala	Tyr	Ser	-	C
5		-14	-13	-12	-11	-10	-9	-8	-7		

In a particularly preferred embodiment the secretion pre sequence used is derived from the sequence of the human albumin secretion pre sequence.

- 10 Thus, for example, the X<sub>1</sub>-X<sub>5</sub> pentapeptide may be fused at its N-terminal end, directly or indirectly, to the C-terminal end of the following sequence SEQ ID NO 8 –

N-Met-Lys-Trp-Val-C

15 SEQ ID No 8

or a conservatively substituted variant thereof, namely -

N-Met-(Lys/Arg/His)-(Phe/Trp/Tyr)-  
(Ile/Leu/Val/Ala/Met)-C

20 SEQ ID No. 33

Additionally or alternatively it may be fused at its C-terminal end, directly or indirectly, to the N-terminal end of at least one of the following sequences –

25 N-Leu-Phe-Leu-Phe-Ser-Ser-Ala-Tyr-Ser-C

SEQ ID No 9

or a conservatively substituted variant thereof, namely -

N-(Ile/Leu/Val/Ala/Met)-(Phe/Trp/Tyr)-(Ile/Leu/Val/Ala/Met)-  
(Phe/Trp/Tyr)-(Ser/Thr/Gly/Tyr/Ala)-(Ser/Thr/Gly/Tyr/Ala)-  
(Ile/Leu/Val/Ala/Met)-(Phe/Trp/Tyr)-(Ser/Thr/Gly/Tyr/Ala)-C

SEQ ID No. 10

5 or

N-Leu-Phe-Leu-Phe-Ser-Ser-Ala-Tyr-Ser-Arg-Ser-Leu-Asp-Lys-Arg-C

SEQ ID No 11

or

N-Leu-Phe-Leu-Phe-Ser-Ser-Ala-Tyr-Ser-Arg-Gly-Val-Phe-Arg-Arg-C

10

SEQ ID No. 30

The sequence given in SEQ ID No 9 represents the final nine amino acids of the natural human albumin pre sequence. In the case of SEQ ID No 11, this is fused to the final six amino acids of one of the two principal fused leader sequences of WO 90/01063 and, in the case of SEQ ID No. 30, SEQ ID No. 9 is fused to the final six amino acids of the natural human albumin pro sequence.

Preferably, in each case, X<sup>1</sup> is F, X<sup>2</sup> is I, X<sup>3</sup> is V, X<sup>4</sup> is S or T and X<sup>5</sup> is I.

20

In a preferred embodiment, the pentapeptide is fused at its N-terminal to the C-terminal of sequence of SEQ ID NO 8 or a conservatively substituted variant thereof and is fused at its C-terminal to the N-terminal of the sequence of SEQ ID NO 9, a conservatively substituted variant thereof, SEQ ID No. 10, 11 or 30, thereby to form, for example, one of the following sequences –

N-Met-Lys-Trp-Val-X<sub>1</sub>-X<sub>2</sub>-X<sub>3</sub>-X<sub>4</sub>-X<sub>5</sub>-  
Leu-Phe-Leu-Phe-Ser-Ser-Ala-Tyr-Ser-C

30

SEQ ID No 12

or

N-Met-Lys-Trp-Val-X<sub>1</sub>-X<sub>2</sub>-X<sub>3</sub>-X<sub>4</sub>-X<sub>5</sub>-(Ile/Leu/Val/Ala/Met)-(Phe/Trp/Tyr)-  
 (Ile/Leu/Val/Ala/Met)-(Phe/Trp/Tyr)-(Ser/Thr/Gly/Tyr/Ala)-  
 (Ser/Thr/Gly/Tyr/Ala)-(Ile/Leu/Val/Ala/Met)-(Phe/Trp/Tyr)-  
 (Ser/Thr/Gly/Tyr/Ala)-C

**SEQ ID No 13**

or

N-Met-Lys-Trp-Val-X<sub>1</sub>-X<sub>2</sub>-X<sub>3</sub>-X<sub>4</sub>-X<sub>5</sub>-  
 Leu-Phe-Leu-Phe-Ser-Ser-Ala-Tyr-Ser-Arg-Ser-Leu-Asp-Lys-Arg-C

**SEQ ID No 14**

N-Met-Lys-Trp-Val-X<sub>1</sub>-X<sub>2</sub>-X<sub>3</sub>-X<sub>4</sub>-X<sub>5</sub>-  
 Leu-Phe-Leu-Phe-Ser-Ser-Ala-Tyr-Ser-Arg-Gly-Val-Phe-Arg-Arg-C

**SEQ ID No 31**

wherein X<sub>1</sub>-X<sub>5</sub> are as defined above, or a conservatively substituted variant thereof, as defined above.

An especially preferred embodiment has, as the secretion pre sequence, the sequence of SEQ ID NO 28 -

N-Met-Lys-Trp-Val-Phe-Ile-Val-Ser-Ile-Leu-Phe-Leu-Phe-Ser-Ser-Ala-  
 Tyr-Ser-C

**SEQ ID No 28**

i.e. the pre sequence is derived from the human serum albumin secretion pre sequence, X<sub>1</sub>, X<sub>2</sub>, X<sub>3</sub>, X<sub>4</sub> and X<sub>5</sub> are at positions -20, -19, -18, -17 and -16, and X<sub>1</sub>, X<sub>2</sub>, X<sub>3</sub>, X<sub>4</sub> and X<sub>5</sub> are as defined by SEQ ID No.7.

As is apparent from above, a secretion pre sequence as defined above, such as the sequences of SEQ ID Nos 12 or 28, may be combined with secretion pro sequences to form functional pre-pro secretion sequences. In a preferred embodiment, a pre sequence motif is fused by a peptide bond at its C-terminal end to the N-terminal amino acid of a secretion pro sequence motif, thereby to form a pre-pro sequence motif. It may be preferable to use a pro sequence derived from the immature version of the mature protein to which the leader sequence is, or is intended to be, attached. It may also be preferable to use the pro sequence that is associated in nature with the unmodified pre sequence or a pro sequence, or part thereof, from an related leader.

Preferably, the pro sequence terminates at its C-terminus in a dibasic pair of amino acids, i.e. each is Lys or Arg.

Typically the secretion pro sequence motif is an albumin secretion pro sequence or variant thereof, such a variant including the dibasic pair of amino acids and having only conservative substitutions at the other positions, usually a human albumin secretion pro sequence, i.e. having the sequence N-Arg-Gly-Val-Phe-Arg-Arg-C or variant thereof. In another preferred embodiment the pro sequence comprises the sequence of the whole or part of the yeast MF $\alpha$ -1 secretion pro sequence, i.e. N-Ser-Leu-Asp-Lys-Arg-C or variant thereof as defined for the albumin pro sequence.

In comparison with the corresponding parts of the leader defined in WO 90/01063 and the human albumin leader, a polypeptide of the present invention has at least four amino acid changes namely Ser-20Phe or Trp or Tyr; Phe-19Ile or Leu or Val or Ala or Met; Ile-18Leu or Val or Ala or Met; and Leu-16Ile or Val or Ala or Met, where the notation means that, taking the first-named mutation as an example, the serine residue at position -20

(i.e. minus twenty relative to the N-terminus of the mature protein that is to be secreted using the leader sequence) is changed to a phenylalanine residue. This is exemplified in Fig. 1.

- 5 One preferred pre-pro sequence comprises the sequence:

MKWVFIVSILFLFSSAYSR<sup>Y1</sup><sup>Y2</sup><sup>Y3</sup><sup>Y4</sup><sup>Y5</sup>

- wherein <sup>Y1</sup> is Gly or Ser, <sup>Y2</sup> is Val or Leu, <sup>Y3</sup> is Phe or Asp, <sup>Y4</sup> is Arg or  
10 Lys and <sup>Y5</sup> is Arg or Lys.

In a preferred embodiment, <sup>Y1</sup> is Gly, <sup>Y2</sup> is Val and <sup>Y3</sup> is Phe. In another preferred embodiment <sup>Y1</sup> is Ser, <sup>Y2</sup> is Leu and <sup>Y3</sup> is Asp.

- 15 Typically <sup>Y4</sup> is Arg and <sup>Y5</sup> is Arg. Alternatively it is preferred if <sup>Y4</sup> is Lys and <sup>Y5</sup> is Arg. Another preferred alternative is where <sup>Y4</sup> is Lys and <sup>Y5</sup> is Lys. <sup>Y4</sup> may also be Arg where <sup>Y5</sup> is Lys.

- An especially preferred embodiment has, as the secretion prepro sequence,  
20 the sequence of SEQ ID NO 32

N-Met-Lys-Trp-Val-Phe-Ile-Val-Ser-Ile-Leu-Phe-Leu-Phe-Ser-Ser-Ala-  
Tyr-Ser-Arg-Ser-Leu-Asp-Lys-Arg-C

25

SEQ ID No 32

A second aspect of the invention provides an isolated polynucleotide having a sequence that encodes the motif as defined by the first aspect of the invention.

30

As used herein, the term "isolated" includes the meaning that the polynucleotide, where it is a DNA molecule, is in isolation from at least most of the chromosome on which it is naturally found and, where it is an RNA molecule, is in isolation from an intact cell in which it is naturally transcribed.

5 In other words, the polynucleotide is not claimed in a form in which it has previously existed, such as in nature. Thus, a polynucleotide according to the second aspect of the invention includes a polynucleotide that has been cloned into a bacterial or fungal vector, such as a plasmid, or into a viral vector, such as a bacteriophage. Preferably such clones are in isolation from clones

10 constituting a DNA library of the relevant chromosome.

The linear amino acid sequence can be reverse translated into a DNA sequence using the degenerate standard genetic code (Fig.2) in which most amino acids are encoded by more than one trinucleotide codon.

15

For example, a DNA sequence encoding the peptide defined as SEQ ID 1 would be deduced to be:

5'-(TTY/TGG/TAY)-(ATH/TTR or CTN/GTN/GCN/ATG)-(TTR or  
20 CTN/GTN/GCN/ATG)-(AGY or TCN/ACN)-(ATH or  
CTN/GTN/GCN/ATG)-3'

**SEQ ID No 15**

where " 3' " and " 5' " denote the orientation of the polynucleotide  
25 sequence, rather than the actual termini; in other words, the polynucleotide sequence may be joined (e.g. fused or ligated) to other polynucleotide sequences at either end or both ends, and wherein Y, R, H and N are as defined in Fig. 2.

30 Using the same conversion procedure the DNA sequence:

5'-TTY-ATH-GTN-(TCN or AGY)-ATH-3'

SEQ ID No 16

5 would be deduced to encode the polypeptide of SEQ ID No 7.

In the case of a polynucleotide sequence comprising a sequence that encodes a naturally occurring mature protein, such a human albumin, this can be either the naturally occurring coding sequence, such as the human  
10 albumin gene sequence, or a complementary DNA sequence (cDNA) or a cDNA containing one or more introns.

Further sequence modifications may also be introduced, for example into the coding region. A desirable way to modify the DNA encoding the  
15 polypeptide of the invention is to use the polymerase chain reaction as disclosed by Saiki *et al* (1988) *Science* 239, 487-491. In this method the DNA to be enzymatically amplified is flanked by two specific oligonucleotide primers which themselves become incorporated into the amplified DNA. The said specific primers may contain restriction endonuclease recognition sites  
20 which can be used for cloning into expression vectors using methods known in the art.

The polynucleotide encoding a leader sequence of the invention is most conveniently made by chemical synthesis of an oligonucleotide, followed  
25 by ligation to the other elements of the genetic construct, by methods that are well known in this art and described in more detail below.

Where it is desirable to modify the polynucleotide that encodes mature albumin, this may be most conveniently achieved by site-directed  
30 mutagenesis or PCR mutagenesis, starting from the natural cDNA sequence,

or from assembling synthetic oligonucleotides. Again, such techniques are standard in this art and are in any case set out in more detail below.

Modification to the coding sequence can be advantageous because, within a particular organism, the polynucleotide sequences encoding some highly expressed proteins favour some codons over others for a particular amino acid; this is called codon bias. In a preferred embodiment of a second aspect of the invention the standard genetic code can be reduced to the preferred codons for the host organism of choice. In an especially preferred embodiment of the second aspect of the invention the standard genetic code can be reduced to the preferred codons of yeast. (See Table 4 of Sharp and Crowe (1991) *Yeast* 7, 657-678.) Advantageously this list of preferred yeast codons is modified by inclusion of the asparagine codon 5'-GAT-3' (Fig.3).

Using the peptide sequence of SEQ ID No 1 as an example, the codon biased DNA sequence encoding this peptide in yeast may be deduced to be:

5'-(TTC/TGG/TAC)-(ATY/TTG/GTY/GCT/ATG)-  
(TTG/GTY/GCT/ATG)-(TCY/ACY)-(ATY/GTY/GCT/ATG)-5'

SEQ ID No 17

Using the same conversion procedure the codon-biased degenerate DNA sequence:

5'-TTC-ATY-GTY-TCY-ATY-3'

SEQ ID No 18

would be deduced for the especially preferred polypeptide motif having the sequence of SEQ ID No 7, although the most preferred codon-biased DNA

sequence encoding a polypeptide motif having the sequence of SEQ ID No. 7 is -

TTCATCGTCTCCATT

SEQ ID No. 34

5

Using the genetic code given in Fig.2 or the preferred codon bias tables available for the intended host or the preferred codon bias given in Fig.3, the same conversion procedure can be used to convert any desired amino acid sequence into a partially redundant polynucleotide sequence. The amino acid sequences, which can be converted into a DNA sequence by this method can be taken from, but not limited to, polypeptides according to the first aspect of the invention. For example, the sequence of a coding region for mature human albumin can be derived in this way. EP 308 381 discloses a partially yeast-codon-optimised coding sequence for human albumin. SEQ ID No. 20 herein is further such sequence. Advantageously, where the DNA sequence redundancy permits, restriction sites can be introduced at domain and sub-domain boundaries, without perturbing the encoded amino acid sequence (or the codon bias if Fig.3 is used).

10

20 The remaining DNA sequence redundancies can be resolved and the number of occurrences of alternative codons equalised for each amino acid with redundant DNA sequences. Advantageously, DNA sequences representing possible transcription terminator sequences can be removed or reduced where possible by utilising the DNA sequence redundancy of the degenerate codons. Finally the balance of alternative codons for amino acids with redundant DNA sequences can be re-equalised but without conflicting with the previous modifications

25

A polynucleotide according to the second aspect of the invention can be directly or indirectly fused to one or more other nucleotide sequences at its

30

5' and/or 3' ends, for example to form a complete gene or expression cassette. Thus, the expression cassette will desirably also contain sites for transcription initiation and termination, and in the transcribed region, a ribosome binding site for translation initiation. (Hastings *et al*, WO 98/16643, published 23 April 1998.)

Accordingly, the second aspect of the present invention includes a polynucleotide comprising a DNA sequence that is a contiguous or non-contiguous fusion of a DNA encoding a heterologous protein with either a DNA sequence encoding a polypeptide according to the first aspect of the present invention, particularly wherein the desired protein is albumin, or a variant or fragment thereof. In this context, the term "heterologous protein" means that it is not the same as the "desired protein", i.e. does not form a homodimer.

Accordingly, the polynucleotide may be directly or indirectly fused to a promoter (an expression control element formed by a DNA sequence that permits binding of RNA polymerase and transcription to occur) at its 5' end and/or to other regulatory sequences, such as, at its 3' end, translation termination sequences. Thus a polynucleotide may be operably linked to one or more regulatory regions, usually transcription regulatory regions. By "operably linked" is meant that the regulatory region is linked in such a way that it is able to exert an effect on the polynucleotide sequence. The choice of which regulatory region to use will be partially dependant upon the expected host (i.e. the intended expression system) and the selection of the preferred sequence will be known to those skilled in the art

Many expression systems are known, including systems employing: bacteria (eg. *Bacillus subtilis* or *Escherichia coli*) transformed with, for example, recombinant bacteriophage, plasmid or cosmid DNA expression vectors;

yeasts (eg. *Saccharomyces cerevisiae* or *Pichia pastoris*) transformed with, for example, yeast expression vectors; insect cell systems transformed with, for example, viral expression vectors (eg. baculovirus); plant cell systems transfected with, for example viral or bacterial expression vectors; animal cell systems, either in cell culture, transgenic or as gene therapy, transfected with, for example, adenovirus expression vectors. The host cell is preferably a yeast (and most preferably a *Saccharomyces* species such as *S. cerevisiae* or a *Pichia* species such as *P. pastoris*).

Accordingly, a third aspect of the present invention provides a host cell transformed with a polynucleotide according to the second aspect of the present invention. The host cell can be either prokaryotic or eukaryotic. Bacterial cells are preferred prokaryotic host cells, particularly if they can secrete proteins, as can some species of *Bacillus* and *Escherichia*. Preferred eukaryotic host cells include plants, fungi, yeast and animal cells, preferably vertebrate cells, more preferably mammalian cells, such as those from a mouse, rat, cow, sheep, goat, pig, buffalo, yak, horse or other domesticated animal, monkey or human. Suitable human cells include cells from a human fibroblastic cell line. Thus a host cell may be a transgenic cell of a mammal *in situ*, and may thus be the result of a gene therapy approach or of the production of a transgenic individual. In the latter case it is preferred that the individual is a non-human mammal.

Exemplary genera of bacterial hosts include *E.coli* and *Bacillus subtilis*.

25

Exemplary genera of plant hosts include spermatophytes, pteridophytes (e.g. ferns, clubmosses, horsetails), bryophytes (e.g. liverworts and mosses), and algae. Typically the plant host cell will be derived from a multicellular plant, usually a spermatophyte, such as a gymnosperm or an angiosperm.

Suitable gymnosperms include conifers (e.g. pines, larches, firs, spruces and

cedars), cycads, yews and ginkos. More typically the plant host cell is the cell of an angiosperm, which may be a monocotyledonous or dicotyledonous plant, preferably a crop plant. Preferred monocotyledonous plants include maize, wheat, barley, sorghum, onion, oats, orchard grass and other *Pooideae*. Preferred dicotyledonous crop plants include tomato, potato, sugarbeet, cassava, cruciferous crops (including oilseed rape), linseed, tobacco, sunflower, fibre crops such as cotton, and leguminous plants such as peas, beans, especially soybean, and alfalfa. The host cell may thus be an autonomous cell, for example the cell of a unicellular plant or a cell maintained in cell culture, or it may be a cell *in situ* in a multicellular plant. Accordingly the present invention contemplates the production of whole transgenic plants, which preferably retain a stable and heritable transgenic phenotype.

Exemplary genera of fungal hosts include *Aspergillus* (e.g. *A. niger* and *A. oryzae*), *Streptomyces*, *Penicillium* and yeasts. Exemplary genera of yeast contemplated to be useful in the practice of the present invention are *Pichia* (*Hansenula*), *Saccharomyces*, *Kluyveromyces*, *Candida*, *Torulopsis*, *Torulaspora*, *Schizosaccharomyces*, *Citeromyces*, *Pachysolen*, *Debaromyces*, *Metschnikowia*, *Rhodosporidium*, *Leucosporidium*, *Botryosascus*, *Sporidiobolus*, *Endomycopsis*, and the like. Preferred genera are those selected from the group consisting of *Pichia* (*Hansenula*), *Saccharomyces*, *Kluyveromyces* and *Yarrowia*. Examples of *Saccharomyces* spp. are *S. cerevisiae*, *S. italicus* and *S. rouxii*. Examples of *Kluyveromyces* spp. are *K. fragilis* and *K. lactis*. Examples of *Pichia* (*Hansenula*) are *P. pastoris*, *P. anomala* and *P. capsulata*. *Y. lipolytica* is an example of a suitable *Yarrowia* species. Yeast host cells include YPH499, YPH500 and YPH501 which are generally available from Stratagene Cloning Systems, La Jolla, CA 92037, USA.

Preferred mammalian host cells include Chinese hamster ovary (CHO) cells available from the ATCC as CCL61, NIH Swiss mouse embryo cells NIH/3T3 available from the ATCC as CRL 1658, and monkey kidney-derived COS-1 cells available from the ATCC as CRL 1650. Preferred insect cells are  
5 Sf9 cells which can be transfected with baculovirus expression vectors.

As discussed above, the choice of polynucleotide regulatory region will be partly dependent on the nature of the intended host.

10 Promoters suitable for use in bacterial host cells include the *E. coli lacI* and *lacZ* promoters, the T3 and T7 promoters, the *gpt* promoter, the phage  $\lambda$  PR and PL promoters, the *phoA* promoter and the *trp* promoter. Promoter sequences compatible with exemplary bacterial hosts are typically provided in plasmid vectors containing convenient restriction sites for insertion of a DNA  
15 segment of the present invention.

Eukaryotic promoters include the CMV immediate early promoter, the HSV thymidine kinase promoter, the early and late SV40 promoters and the promoters of retroviral LTRs. Other suitable promoters will be known to  
20 those skilled in the art.

Suitable promoters for *S. cerevisiae* include those associated with the *PGK1* gene, *GAL1* or *GAL10* genes, *CYC1*, *PHO5*, *TRP1*, *ADH1*, *ADH2*, the genes for glyceraldehyde-3-phosphate dehydrogenase, hexokinase, pyruvate  
25 decarboxylase, phosphofructokinase, triose phosphate isomerase, phosphoglucose isomerase, glucokinase,  $\alpha$ -mating factor pheromone, a-mating factor pheromone, the *PRB1* promoter, the *GPD1* promoter, and hybrid promoters involving hybrids of parts of 5' regulatory regions with parts of 5' regulatory regions of other promoters or with upstream activation  
30 sites (e.g. the promoter of EP-A-258 067).

Convenient regulatable promoters for use in *Schizosaccharomyces pombe*, another suitable host cell, are the thiamine-repressible promoter from the *nmt* gene as described by Maundrell (1990) *J. Biol. Chem.* **265**, 10857-10864 and the glucose-repressible *fbp1* gene promoter as described by Hoffman & Winston (1990) *Genetics* **124**, 807-816.

Suitable promoters, transformation protocols and culture conditions for *Pichia* can be found in US 5 986 062 (incorporated herein by reference). For example, preparation of an HSA-producing host (or an HSA-producing strain) may be effected using a process in which a recombinant plasmid is introduced into chromosome (JP-A-3-72889 corresponding to EP-A-399455), a process in which HSA is expressed in yeast (JP-A-60-41487 corresponding to EP-A-123544, JP-A-63-39576 corresponding to EP-A-248657 and JP-A-63-74493 corresponding to EP-A-251744) and a process in which HSA is expressed in *Pichia* (JP-A-2-104290 corresponding to EP-A-344459). Culturing of an HSA-producing host (an HSA production process) may be carried out using known processes, such as those referred to in US 5,986,062, for example in accordance with a process disclosed in JP-A-3-83595 or JP-A-4-293495 (corresponding to EP-A-504823). The medium for culturing a transformed host may be prepared in accordance with US 5,986,062 and culturing of a host may be carried out preferably at 15 to 43°C (more preferably 20 to 30°C) for 1 to 1,000 hours, by means of static or shaking culturing or batch, semi-batch or continuous culturing under agitation and aeration in accordance with the disclosures of US 5,986,062.

Suitable transcription termination signals are well known in the art. Where the host cell is eukaryotic, the transcription termination signal is preferably derived from the 3' flanking sequence of a eukaryotic gene, which contains

proper signals for transcription termination and polyadenylation. Suitable 3' flanking sequences may, for example, be those of the gene naturally linked to the expression control sequence used, i.e. may correspond to the promoter. Alternatively, they may be different. In that case, and where the  
5 host is a yeast, preferably *S. cerevisiae*, then the termination signal of the *S. cerevisiae ADH1* gene is preferred.

Thus a polynucleotide according to the second aspect of the present invention can be developed for any desired host by using methods such as  
10 those described above.

A DNA sequence encoding mature human albumin can be developed from DNA fusions between the native gene, cDNA or a cDNA containing one or more introns, as described above and a codon biased human albumin DNA  
15 sequence derived by the method described above.

SEQ IQ No 19 is a polynucleotide sequence that comprises 22 nucleotides 5' to the translation initiation site, a preferred polynucleotide coding sequence for the secretion leader sequence SEQ ID No. 32 and a mature  
20 human albumin coding region SEQ ID No 20. The coding sequence ends with a translation stop codon. Typically, this is TGA, TAG or TAA, although TAA is the most efficient in yeast. Preferably, further translation stop codons (preferably each is TAA), usually one or two, are included, preferably adjacent each other or with no more than 3 base pairs between  
25 each pair of stop codons. SEQ IQ No 19 is flanked at both ends by appropriate cloning sites.

The polynucleotide of the second aspect of the invention may also be joined to a wide variety of other DNA sequences for introduction into an appropriate  
30 host. The companion sequence(s) will depend upon the nature of the host, the

manner of the introduction of the polynucleotide into the host, and whether episomal maintenance or integration is desired. For example, the vectors can include a prokaryotic replicon, such as the Col E1 *ori*, for propagation in a prokaryote, even if the vector is to be used for expression in other, non-prokaryotic cell types.

Generally, a polynucleotide according to the second aspect of the invention is inserted into an expression vector, such as a plasmid, in proper orientation and correct reading frame for expression.

Thus, the polynucleotide may be used in accordance with known techniques, appropriately modified in view of the teachings contained herein, to construct an expression vector, including, but not limited to integration vectors, centromeric vectors and episomal vectors.

Thus in one embodiment of the second aspect of the invention, the polynucleotide is a vector.

Typical prokaryotic vector plasmids are: pUC18, pUC19, pBR322 and pBR329 available from Biorad Laboratories (Richmond, CA, USA); p*Trc*99A, pKK223-3, pKK233-3, pDR540 and pRIT5 available from Pharmacia (Piscataway, NJ, USA); pBS vectors, Phagescript vectors, Bluescript vectors, pNH8A, pNH16A, pNH18A, pNH46A available from Stratagene Cloning Systems (La Jolla, CA 92037, USA).

A typical mammalian cell vector plasmid is pSVL available from Pharmacia (Piscataway, NJ, USA). This vector uses the SV40 late promoter to drive expression of cloned genes, the highest level of expression being found in T antigen-producing cells, such as COS-1 cells. An example of an inducible mammalian expression vector is pMSG, also available from Pharmacia

(Piscataway, NJ, USA). This vector uses the glucocorticoid-inducible promoter of the mouse mammary tumour virus long terminal repeat to drive expression of the cloned gene.

- 5 Useful yeast episomal plasmid vectors are pRS403-406 and pRS413-416 and are generally available from Stratagene Cloning Systems (La Jolla, CA 92037, USA), YEp24 (Botstein, D., *et al.* (1979) *Gene* 8, 17-24), and YEplac122, YEplac195 and YEplac181 (Gietz, R.D. and Sugino. A. (1988) *Gene* 74, 527-534). Other yeast plasmids are described in WO 90/01063 and EP 424 117, as  
10 well as the "disintegration vectors of EP-A-286 424. Plasmids pRS403, pRS404, pRS405 and pRS406 are Yeast Integrating plasmids (YIps) and incorporate the yeast selectable markers *HIS3*, *TRP1*, *LEU2* and *URA3*, as are YIplac204, YIplac211 and YIplac128 (Gietz, R.D. and Sugino. A. (1988) *Gene* 74, 527-534). Plasmids pRS413-416 are Yeast Centromere plasmids  
15 (YCps) as are YCplac22, YCplac33 and YCplac111 (Gietz, R.D. and Sugino. A. (1988) *Gene* 74, 527-534).

Methods well known to those skilled in the art can be used to construct expression vectors containing the coding sequence and, for example  
20 appropriate transcriptional or translational controls. One such method involves ligation via cohesive ends. Compatible cohesive ends can be generated on the DNA fragment and vector by the action of suitable restriction enzymes. These ends will rapidly anneal through complementary base pairing and remaining nicks can be closed by the action of DNA ligase.

25

A further method uses synthetic double stranded oligonucleotide linkers and adaptors. DNA fragments with blunt ends are generated by bacteriophage T4 DNA polymerase or *E.coli* DNA polymerase I which remove protruding 3' termini and fill in recessed 3' ends. Synthetic linkers and pieces of blunt-  
30 ended double-stranded DNA which contain recognition sequences for defined

restriction enzymes, can be ligated to blunt-ended DNA fragments by T4 DNA ligase. They are subsequently digested with appropriate restriction enzymes to create cohesive ends and ligated to an expression vector with compatible termini. Adaptors are also chemically synthesised DNA fragments  
5 which contain one blunt end used for ligation but which also possess one preformed cohesive end. Alternatively a DNA fragment or DNA fragments can be ligated together by the action of DNA ligase in the presence or absence of one or more synthetic double stranded oligonucleotides optionally containing cohesive ends.

10

Synthetic linkers containing a variety of restriction endonuclease sites are commercially available from a number of sources including Sigma-Genosys Ltd, London Road, Pampisford, Cambridge, United Kingdom.

15 Vectors of the invention thus produced may be used to transform an appropriate host cell for the expression and production of a polypeptide comprising a sequence as defined in the first aspect of the invention. Such techniques include those disclosed in US Patent Nos. 4,440,859 issued 3 April 1984 to Rutter *et al*, 4,530,901 issued 23 July 1985 to Weissman, 4,582,800  
20 issued 15 April 1986 to Crawl, 4,677,063 issued 30 June 1987 to Mark *et al*, 4,678,751 issued 7 July 1987 to Goeddel, 4,704,362 issued 3 November 1987 to Itakura *et al*, 4,710,463 issued 1 December 1987 to Murray, 4,757,006 issued 12 July 1988 to Toole, Jr. *et al*, 4,766,075 issued 23 August 1988 to Goeddel *et al* and 4,810,648 issued 7 March 1989 to Stalker, all of which are  
25 incorporated herein by reference.

Transformation of appropriate cell hosts with a DNA construct of the present invention is accomplished by well known methods that typically depend on the type of vector used. With regard to transformation of prokaryotic host  
30 cells, see, for example, Cohen *et al* (1972) *Proc. Natl. Acad. Sci. USA* 69,

2110 and Sambrook *et al* (2001) *Molecular Cloning, A Laboratory Manual*,  
3<sup>rd</sup> Ed. Cold Spring Harbor Laboratory, Cold Spring Harbor, NY.  
Transformation of yeast cells is described in Sherman *et al* (1986) *Methods In*  
*Yeast Genetics, A Laboratory Manual*, Cold Spring Harbor, NY. The method  
5 of Beggs (1978) *Nature* 275, 104-109 is also useful. Methods for the  
transformation of *S. cerevisiae* are taught generally in EP 251 744, EP 258  
067 and WO 90/01063, all of which are incorporated herein by reference.  
With regard to vertebrate cells, reagents useful in transfecting such cells, for  
example calcium phosphate and DEAE-dextran or liposome formulations, are  
10 available from Stratagene Cloning Systems, or Life Technologies Inc.,  
Gaithersburg, MD 20877, USA.

Electroporation is also useful for transforming cells and is well known in the  
art for transforming yeast cell, bacterial cells and vertebrate cells. Methods  
15 for transformation of yeast by electroporation are disclosed in Becker &  
Guarente (1990) *Methods Enzymol.* 194, 182.

Physical methods may be used for introducing DNA into animal and plant  
cells. For example, microinjection uses a very fine pipette to inject DNA  
20 molecules directly into the nucleus of the cells to be transformed. Another  
example involves bombardment of the cells with high-velocity  
microprojectiles, usually particles of gold or tungsten that have been coated  
with DNA.

25 Plants may be transformed in a number of art-recognised ways. Those  
skilled in the art will appreciate that the choice of method might depend on  
the type of plant targeted for transformation. Examples of suitable methods  
of transforming plant cells include microinjection (Crossway *et al.*,  
*BioTechniques* 4:320-334 (1986)), electroporation (Riggs *et al.*, *Proc. Natl.*  
30 *Acad. Sci. USA* 83:5602-5606 (1986), *Agrobacterium*-mediated

transformation (Hinchee *et al.*, *Biotechnology* 6:915-921 (1988); see also, Ishida *et al.*, *Nature Biotechnology* 14:745-750 (1996) for maize transformation), direct gene transfer (Paszkowski *et al.*, *EMBO J.* 3:2717-2722 (1984); Hayashimoto *et al.*, *Plant Physiol.* 93:857-863 (1990) (rice)),  
5 and ballistic particle acceleration using devices available from Agracetus, Inc., Madison, Wisconsin and Dupont, Inc., Wilmington, Delaware (see, for example, Sanford *et al.*, U.S. Patent 4,945,050; and McCabe *et al.*, *Biotechnology* 6:923-926 (1988)). See also, Weissinger *et al.*, *Annual Rev. Genet.* 22:421-477 (1988); Sanford *et al.*, *Particulate Science and*  
10 *Technology* 5:27-37 91987) (onion); Svab *et al.*, *Proc. Natl. Acad. Sci. USA* 87:8526-8530 (1990) (tobacco chloroplast); Christou *et al.*, *Plant Physiol.* 87:671-674 (1988) (soybean); McCabe *et al.*, *Bio/Technology* 6:923-926 (1988) (soybean); Klein *et al.*, *Proc. Natl. Acad. Sci. USA*, 85:4305-4309 (1988) (maize); Klein *et al.*, *Bio/Technology* 6:559-563 (1988) (maize);  
15 Klein *et al.*, *Plant Physiol.* 91:440-444 (1988) (maize); Fromm *et al.*, *Bio/Technology* 8:833-839 (1990); and Gordon-Kamm *et al.*, *Plant Cell* 2: 603-618 (1990) (maize); Koziel *et al.*, *Biotechnology* 11:194-200 (1993) (maize); Shimamoto *et al.*, *Nature* 338:274-277 (1989) (rice); Christou *et al.*, *Biotechnology* 9:957-962 (1991) (rice); Datta *et al.*, *Bio/Technology*  
20 8:736-740 (1990) (rice); European Patent Application EP-A-332 581 (orchardgrass and other Pooideae); Vasil *et al.*, *Biotechnology* 11:1553-1558 (1993) (wheat); Weeks *et al.*, *Plant Physiol.* 102:1077-1084 (1993) (wheat); Wan *et al.*, *Plant Physiol.* 104:37-48 (1994) (barley); Jahne *et al.*, *Theor. Appl. Genet.* 89:525-533 (1994) (barley); Umbeck *et al.*,  
25 *Bio/Technology* 5:263-266 (1987) (cotton); Casas *et al.*, *Proc. Natl. Acad. Sci. USA* 90:11212-11216 (1993) (sorghum); Somers *et al.*, *Bio/Technology* 10:1589-1594 (1992) (oat); Torbert *et al.*, *Plant Cell Reports* 14:635-640 (1995) (oat); Weeks *et al.*, *Plant Physiol.* 102:1077-1084 (1993) (wheat); Chang *et al.*, WO 94/13822 (wheat) and Nehra *et al.*, *The Plant Journal*  
30 5:285-297 (1994) (wheat). *Agrobacterium*-mediated transformation is

generally ineffective for monocotyledonous plants for which the other methods mentioned above are preferred.

5 Generally, the vector will transform not all of the hosts and it will therefore be necessary to select for transformed host cells. One selection technique involves incorporating into the expression vector a DNA sequence marker, with any necessary control elements, that codes for a selectable trait in the transformed cell. These markers include dihydrofolate reductase, G418 or neomycin resistance for eukaryotic cell culture, and tetracyclin, kanamycin or  
10 ampicillin resistance genes for culturing in *E.coli* and other bacteria. Alternatively, the gene for such selectable trait can be on another vector, which is used to co-transform the desired host cell.

15 The marker gene can be used to identify transformants but it is desirable to determine which of the cells contain recombinant DNA molecules and which contain self-ligated vector molecules. This can be achieved by using a cloning vector where insertion of a DNA fragment destroys the integrity of one of the genes present on the molecule. Recombinants can therefore be identified because of loss of function of that gene.

20 Another method of identifying successfully transformed cells involves growing the cells resulting from the introduction of an expression construct of the present invention to produce the polypeptide of the invention. Cells can be harvested and lysed and their DNA content examined for the presence of the  
25 DNA using a method such as that described by Southern (1975) *J. Mol. Biol.* 98, 503 or Berent *et al* (1985) *Biotech.* 3, 208. Alternatively, the presence of the mature protein in the supernatant of a culture of a transformed cell can be detected using antibodies.

In addition to directly assaying for the presence of recombinant DNA, successful transformation can be confirmed by well known immunological methods when the recombinant DNA is capable of directing the expression of the protein. For example, cells successfully transformed with an expression  
5 vector produce proteins displaying appropriate antigenicity. Samples of cells suspected of being transformed are harvested and assayed for the protein using suitable antibodies.

Thus, in addition to the transformed host cells themselves, the present  
10 invention also contemplates a culture of those cells, preferably a monoclonal (clonally homogeneous) culture, or a culture derived from a monoclonal culture, in a nutrient medium.

Accordingly, in a fourth aspect of the present invention there is provided a cell  
15 culture comprising a cell according to the third aspect of the invention and culture medium. Typically the culture medium will contain mature polypeptide that results from the expression of a polypeptide according to the first aspect of the present invention within the expression system and, usually, by further translational processing, such as the removal of the pre  
20 and/or pro sequences.

Methods for culturing prokaryotic host cells, such as *E.coli*, and eukaryotic host cells, such as mammalian cells are well known in the art. Methods for culturing yeast are generally taught in EP 330 451 and EP 361 991.

25

Allowing host cells that have been transformed by the recombinant DNA of the invention to be cultured for a sufficient time and under appropriate conditions known to those skilled in the art in view of the teachings disclosed herein permits the expression of the polypeptide according to the first aspect  
30 of the present invention. The thus produced polypeptide may be further

processed by the host cell, such that the pre and/or pro sequences are removed. Accordingly the "mature" desired protein may differ from the protein as originally translated.

5 Thus the invention also provides, as a fifth aspect, a process for producing a mature desired protein as defined above. The process comprises the step of culturing a cell according to the third aspect of the invention in a culture medium wherein the cell, as a result of the expression of a polypeptide as defined in the first aspect of the invention, secretes a mature desired protein,  
10 where it accumulates either in the periplasmic space, the culture medium or both, but preferably into the culture medium. The culture medium, which contains the secreted desired protein, may then be separated from the cell(s) in the cell culture. Secreted proteins associated with the cell wall can generally be disassociated therefrom using lytic enzymes under osmotic supporting (e.g. sorbitol) conditions (which gently release the secreted  
15 protein selectively). See Elango *et al.*, *J. Biol. Chem.* **257**: 1398-1400 (1982). Examples of lytic enzymes suitable for this purpose include lyticase, Zymolyase-60,000, and Glusulase, all of which are commercially available, for example, the case of the latter two, from Seikagaku Kogyo or  
20 Kirin Brewery, and from Boehringer Mannheim, respectively.

Preferably, following the isolation of the culture medium, the mature desired protein is separated from the medium. Even more preferably the thus obtained mature desired protein is further purified.

25

The desired mature protein may be extracted from the culture medium by many methods known in the art. For example purification techniques for the recovery of recombinantly expressed albumin have been disclosed in: WO 92/04367, removal of matrix-derived dye; EP 464 590, removal of  
30 yeast-derived colorants; EP 319 067, alkaline precipitation and subsequent

application of the albumin to a lipophilic phase; and WO 96/37515, US 5 728 553 and WO 00/44772, which describe complete purification processes; all of which are incorporated herein by reference. Proteins other than albumin may be purified from the culture medium by any technique that has  
5 been found to be useful for purifying such proteins, since the modified leader sequence of the invention will not affect the mature protein *per se*.

Such well-known methods include ammonium sulphate or ethanol precipitation, acid extraction, anion or cation exchange chromatography,  
10 phosphocellulose chromatography, hydrophobic interaction chromatography, affinity chromatography, hydroxylapatite chromatography and lectin chromatography. Most preferably, high performance liquid chromatography ("HPLC") is employed for purification.

15 The resulting protein may be used for any of its known utilities, which, in the case of albumin, include i.v. administration to patients to treat severe burns, shock and blood loss, supplementing culture media, and as an excipient in formulations of other proteins.

20 Although it is possible for a therapeutically useful desired protein obtained by a process of the of the invention to be administered alone, it is preferable to present it as a pharmaceutical formulation, together with one or more acceptable carriers or diluents. The carrier(s) or diluent(s) must be "acceptable" in the sense of being compatible with the desired protein and not  
25 deleterious to the recipients thereof. Typically, the carriers or diluents will be water or saline which will be sterile and pyrogen free.

Thus, a sixth aspect of the present invention provides a process wherein a desired protein, obtained by a process according to the fifth aspect of the  
30 invention, is formulated with a therapeutically acceptable carrier or diluent

thereby to produce a therapeutic product suitable for administration to a human or an animal.

5 The therapeutic product may conveniently be presented in unit dosage form and may be prepared by any of the methods well known in the art of pharmacy. Preferred unit dosage products are those containing a daily dose or unit, daily sub-dose or an appropriate fraction thereof, of an active ingredient.

10 It should be understood that in addition to the ingredients particularly mentioned above the therapeutic product may include other agents conventional in the art having regard to the type of product in question.

The invention will now be described in more detail by reference to the following non-limiting Figures and Examples wherein:

15

Figure 1 shows a comparison of a natural HSA leader (having pre and pro regions) (top line) with a fused HSA/MF $\alpha$ -1 leader sequence as disclosed in WO 90/01063 (second line) and a preferred modified leader sequence of the present invention (third line).

\*Means that the human albumin level was too low to quantitate.

- 5 Figure 22 summarises the characteristics of the constructs used in the examples.

•

### **Example 1**

- 10 The *Saccharomyces cerevisiae* *PRB1* promoter was isolated from yeast genomic DNA by PCR using two single stranded oligonucleotides PRBJM1 and PRBJM2:

PRBJM1

15

5'-GCATGCGGCCCGCCCGTAATGCGGTATCGTGAAAGCG-3'

**SEQ ID NO:35**

PRBJM2

- 20 5'GCATAAGCTTACCCACTTCATCTTTGCTTGTTTAG-3'

**SEQ ID NO:36**

- The PCR conditions 40 cycles of 94°C for 30 seconds, 50°C for 40 seconds, 72°C for 120 seconds, followed by 72°C for 600 seconds,  
25 followed by a 4°C hold. The 0.85kb DNA fragment was digested with both *NotI* and *HindIII* and ligated into pBST+, described in WO 97/24445, similarly digested with *NotI* and *HindIII*, to create plasmid pAYE438 (Figure 4). Plasmid pAYE438 was digested with *HindIII* and *BamHI* and ligated with the 0.48kb *HindIII/BamHI ADH1* terminator DNA fragment  
30 from pAYE440 previously disclosed in WO 00/44772, so as to create plasmid pAYE441 (Figure 5). Plasmid pAYE441 was linearised at the

unique *Hind*III site and ligated with the 1.8kb *Hind*III/*Bsu*36I fragment from pAYE309 (Figure 6) previously disclosed (Sleep, D. *et al.* (1991) *Bio/Technology* 9, 183-187 and EP-A-0 431 880 and the double stranded oligonucleotide linker

5

5'-TTAGGCTTATA-3'

SEQ ID NO: 37

3'-CCGAATATTCGA-5'

SEQ ID NO: 38

so as to create pAYE467 (Figure 7). The 3.2kb *Not*I, expression cassette  
10 from pAYE467 was ligated into *Not*I linearised pSAC35 (Sleep *et al.* (1991), *Bio/technology* 9: 183-187), which had been previously treated with calf intestinal phosphatase (CIP) to create plasmid pAYE443 (Figure 8). SEQ IQ No 22 shows a polynucleotide sequence that comprises the coding region of the HSA/MF $\alpha$ -1 fusion leader sequence and the mature human  
15 albumin coding region to be found within the DNA sequence of both pAYE467 and pAYE443. The polynucleotide sequence encoding the HSA/MF $\alpha$ -1 fusion leader sequence was modified by site directed mutagenesis with a single stranded oligonucleotide called CPK1 with the DNA sequence:

20

5'-CT AAA GAG AAA AAG AAT GGA GAC GAT GAA TAC CCA

Ile<sup>-16</sup> Val<sup>-18</sup> Ile<sup>-19</sup> Phe<sup>-20</sup>

CTT CAT CTT TGC-3'

SEQ ID No 23

25

Site directed mutagenesis (SDM) was performed according to standard protocols (Botstein and Shortle, "Strategies and Applications of *In Vitro* Mutagenesis," *Science*, 229: 193-1210 (1985) incorporated herein by  
30 reference) although or other suitable techniques could also be used. The

nucleotide sequence of CPK1 was designed to modify the amino acid sequence of the HSA/MF $\alpha$ -1 fusion leader sequence to introduce the following mutations Thr-20Phe, Phe-19Ile, Ile-18Val and Leu-16Ile, where the numbering (-20 etc) is such that the -1 residue is the C-terminal amino acid of HSA/MF $\alpha$ -1 fusion leader sequence.

The DNA sequence of the mutagenised plasmid was confirmed by dideoxynucleotide sequencing which confirmed that the polynucleotide sequence had been mutagenised to the desired sequence and that no other DNA sequence alterations had been introduced. The new plasmid was named pAYE653 (Figure 9). SEQ IQ No 24 shows a polynucleotide sequence that comprises the coding region of the modified HSA/MF $\alpha$ -1 fusion leader sequence and SEQ IQ No 25 shows a polynucleotide sequence that comprises the coding region of the modified HSA/MF $\alpha$ -1 fusion leader sequence and the mature human albumin coding region to be found within the polynucleotide sequence of pAYE653.

The *NotI* human albumin expression cassette was isolated from pAYE653 and ligated into the unique *NotI* site of plasmid pSAC35 to generate plasmids pAYE655 (Figure 10).

### Example 2

SEQ ID No 19 shows a DNA sequence that comprises: a non-coding region that includes a 5' UTR from the *Saccharomyces cerevisiae* *PRB1* promoter; a polynucleotide region encoding the modified HSA/MF $\alpha$ -1 fusion leader sequence of the invention; a codon optimised coding region for mature human albumin and translation termination sites.

As a control with which to compare the effects of the sequence modifications provided to the leader sequence in SEQ ID No 19, SEQ ID No 40 shows a DNA sequence that is essentially the same as SEQ ID No 19, except that, instead of the 15 polynucleotide region representing the second aspect of the invention, the DNA sequence of SEQ ID No 40 comprises an 15 polynucleotide region encoding the 5 amino acids of an unmodified HSA/MF $\alpha$ -1 fusion leader sequence, namely SFISL.

Both DNA sequences were synthesised by Genosys, Inc (Cambridge, UK) from overlapping single-stranded oligonucleotides.

SEQ ID No 40 was synthesised as a 1.865kb *SacI* - *HindIII* DNA fragment cloned into the *SacI* - *HindIII* sites of plasmid pBSSK- (Stratagene Europe, P.O. Box 12085, Amsterdam, The Netherlands), as plasmid pAYE639 (Figure 11).

The *Saccharomyces cerevisiae* *PRB1* promoter was isolated from yeast genomic DNA by PCR using two single stranded oligonucleotides PRBJM1 and PRBJM3:

20

PRBJM3

5'-GTTAGAATTAGGTTAAGCTTGTTTTTTTATTGGCGATGAA-3'

SEQ ID NO: 39

25

The PCR conditions 40 cycles of 94°C for 30 seconds, 50°C for 40 seconds, 72°C for 120 seconds, followed by 72°C for 600 seconds, followed by a 4°C hold. The 0.81kb DNA fragment was digested with both *NotI* and *HindIII* and ligated into pBST+, described in WO 97/24445, similarly digested with *NotI* and *HindIII*, to create plasmid pAYE439

30

(Figure 12). Plasmid pAYE439 was digested with *Hind*III and *Bam*HI and ligated with the 0.48kb *Hind*III/*Bam*HI *ADH1* terminator DNA fragment from pAYE440 previously disclosed in WO 00/44772, so as to create plasmid pAYE466 (Figure 13).

5

A 1.865kb *Hind*III DNA fragment of SEQ ID No 40 was cloned into the unique *Hind*III site of plasmid pAYE466 to create plasmid pAYE640, which was shown to contain the 1.865kb *Hind*III DNA fragment of SEQ ID No 40 between the *PRB1* promoter and the *ADH1* terminator in the correct orientation for expression from the *PRB1* promoter (Figure 14).

10

Plasmid pAYE640 was digested to completion with *Not*I/*Pvu*I and the *Not*I 3.2kb, *PRB1* promoter/*Hind*III DNA fragment of SEQ ID No 40 gene/*ADH1* terminator expression cassette was purified. A *Not*I/*Pvu*I double digest of pAYE640 was preferable to a single *Not*I digestion because the expression cassette (3.2kb) and pBST+ plasmid backbone (3.15kb) were similar in size. The 3.2kb *Not*I, expression cassette from pAYE640 was ligated into *Not*I linearised pSAC35 (Sleep *et al.* (1991), *Bio/technology* 9: 183-187), which had been previously treated with calf intestinal phosphatase (CIP) to create plasmid pAYE638 (Figure 15). Plasmid pAYE638 was shown to contain the *Not*I HSA expression cassette inserted into the *Not*I site of pSAC35 and orientated so that the expression of the HSA gene was away from the *LEU2* auxotrophic marker and toward the 2 $\mu$ m origin of replication. Plasmid pAYE642 contained the same HSA expression cassette but arranged in the opposite orientation (Figure 15).

15

20

25

SEQ ID No 19 was synthesised as a 1.865kb *Sac*I - *Hind*III DNA fragment cloned into pBSSK- (Stratagene Europe, P.O. Box 12085, Amsterdam, The Netherlands), as plasmid pAYE643 (Figure 16). The DNA sequence which encodes for an HSA/MF $\alpha$ -1 fusion leader sequence-albumin fusion within

30

pAYE643 is given in SEQ ID No 27. The 1.865kb *HindIII* fragment of SEQ ID No 19 was isolated from pAYE643 and ligated into the unique *HindIII* site of pAYE466 to create plasmid pAYE645 (Figure 17). The *NotI* *PRB1* rHA expression cassette was isolated from pAYE645 by digestion with *NotI/PvuI*, and ligated into the unique *NotI* site of pSAC35 to generate plasmids pAYE646 (Figure 18) and pAYE647 (Figure 19). The *NotI* expression cassette within plasmid pAYE646 was orientated in the same direction as plasmid pAYE638 and pAYE443, while the *NotI* expression cassette within plasmid pAYE647 was orientated in the opposite orientation and was the same as plasmid pAYE642.

### Example 3

Three different yeast strains, A, B and C, were transformed to leucine prototrophy with plasmids pAYE443, pAYE638, pAYE646 and pAYE655. The transformants were patched out onto Buffered Minimal Medium (BMM, described by Kerry-Williams, S.M. *et al.* (1998) *Yeast* 14, 161-169) containing 2% (w/v) glucose (BMMD) and incubated at 30°C until grown sufficiently for further analysis. The human albumin productivity of the transformants was analysed from 10mL YEP (1% (w/v) yeast extract; 2% (w/v) bacto peptone) containing 2% (w/v) glucose (YEPD) and BMMD shake flask culture (30°C, 200rpm, 72hr) by rocket immunoelectrophoresis of cell free culture supernatant (Figure 20).

The results showed that the human albumin productivity of all three strains transformed with pAYE638 was approximately 4-5 fold lower than that observed in the same strain transformed with pAYE443 (which both contained the HSA/MF $\alpha$ -1 fusion leader sequence, but encoded by different polynucleotide sequences) in both rich and defined media. Unexpectedly, the human albumin productivity of all three strains transformed with

pAYE646 or pAYE655 was significantly higher than that observed with pAYE638 and similar or slightly greater than that observed for the same strains transformed with pAYE443.

#### 5 Example 4

Yeast strain C [pAYE443], strain C [pAYE655], strain C [pAYE638] and strain C [pAYE646], and strain B [pAYE443] and strain B [pAYE646] were cultivated in high cell density fermentation in both fed-batch and fill & draw procedures. The fed-batch procedure used a medium and control parameters as described in WO 96/37515. The fill & draw procedure used the fed-batch procedure as described above, but additionally included the steps that: upon completion of the feed phase of the fed-batch culture procedure, 90% of the culture volume was removed from the fermenter vessel; and batch medium was added to the remaining 10% volume of the culture (maintaining pH control) prior to the initiation of feed addition, using the medium and control parameters described in WO 96/37515. The human albumin productivity ( $Y_{P/S}$ ) and human albumin concentration (g/L) were assessed by scanning densitometry of SDS-PAGE of cell free whole culture. The biomass yield ( $Y_{X/S}$ ) was also calculated from gravimetric determinations. The results (Fig. 21) indicated that, as seen previously in Example 3, the human albumin productivity ( $Y_{P/S}$ ) and human albumin concentration (g/L) of yeast strains containing the human albumin expression plasmid pAYE638 (native polypeptide sequence but yeast-biased codons) had significantly lower productivity than the same strains containing the human albumin expression plasmid pAYE443 (native polypeptide sequence and natural codon bias for leader and mature albumin) even though the amino acid sequences of both the HSA/MF $\alpha$ -1 fusion leader sequence and the mature human albumin were identical.

When the strain C fermentations were run in fed-batch mode a 16% and 12% increase in human albumin productivity ( $Y_{P/S}$ ) relative to that of Strain C [pAYE443] was observed when Strain C [pAYE655] and Strain C [pAYE646] (human albumin expression plasmids incorporating a modified leader sequence in accordance with the present invention) were each cultured for a comparable length of time, respectively. When the strain B fermentations were run in fed-batch mode a 24% increase in human albumin productivity ( $Y_{P/S}$ ) relative to that of Strain B [pAYE443] was observed when Strain B [pAYE646] (the human albumin expression plasmid incorporating a modified leader sequence in accordance with the present invention) was cultured for a comparable length of time.

When the strain C fermentations were run in fill and draw mode a 13% and 6% increase in human albumin productivity ( $Y_{P/S}$ ) relative to that of Strain C [pAYE443] was observed when Strain C [pAYE655] and Strain C [pAYE646] (the human albumin expression plasmids incorporating modified leader sequence in accordance with the present invention) were each cultured for a comparable length of time, respectively. This increased to 442% and 408% relative to that of Strain C [pAYE638] when Strain C [pAYE655] and Strain C [pAYE646] (the human albumin expression plasmids incorporating a modified leader sequence in accordance with the present invention) were each cultured for a comparable length of time, respectively.

## Summary

Plasmids pAYE443 and pAYE638 both encode human albumin having a leader sequence derived from HSA/MF $\alpha$ -1 fusion leader sequence, but the former uses the natural codon bias of the native polynucleotide sequences, while the latter uses a polynucleotide sequence which is fully codon optimised for yeast expression. Expression of human albumin obtained

from pAYE638 is 4-5 fold lower than that obtained using pAYE443. A polynucleotide sequence encoding a modified leader sequence in accordance with the present invention has been substituted into the polynucleotide sequence encoding the HSA/MF $\alpha$ -1 fusion leader sequence  
5 of both pAYE443 and pAYE638 to create the human albumin expression plasmids pAYE665 and pAYE646, respectively. The introduction of the polypeptide sequence according to the present invention led to a significant improvement in production of the desired polypeptide.

**CLAIMS**

1. A polypeptide comprising
- (i) a leader sequence, the leader sequence comprising
- 5 (a) a secretion pre sequence, and
- (b) the following motif:

10 where  $X_1$  is phenylalanine, tryptophan, or tyrosine,  $X_2$  is isoleucine, leucine, valine, alanine or methionine,  $X_3$  is leucine, valine, alanine or methionine,  $X_4$  is serine or threonine and  $X_5$  is isoleucine, valine, alanine or methionine; and

- 15 (ii) a desired protein heterologous to the leader sequence.

2. A polypeptide according to Claim 1 wherein  $X_1$  is phenylalanine.

3. A polypeptide according to Claim 1 or 2 wherein  $X_2$  is isoleucine.

20

4. A polypeptide according to any one of the preceding claims wherein  $X_3$  is valine.

5. A polypeptide according to any one of the preceding claims wherein

25 the amino acids of the motif are included in the polypeptide as substitutes, for naturally occurring amino acids.

6. A polypeptide according to any one of the preceding claims wherein  $X_5$  is isoleucine.

30

7. A polypeptide according to any one of the preceding claims wherein the motif is -Phe-Ile-Val-Ser-Ile-.
8. A polypeptide according to any one of the preceding claims wherein the secretion pre sequence is an albumin secretion pre sequence or a variant thereof.
9. A polypeptide according to Claim 8 wherein  $X_1$ ,  $X_2$ ,  $X_3$ ,  $X_4$  and  $X_5$  are at positions -20, -19, -18, -17 and -16, respectively, in place of the naturally occurring amino acids at those positions, wherein the numbering is such that the -1 residue is the C-terminal amino acid of the native albumin secretion pro sequence and where  $X_1$ ,  $X_2$ ,  $X_3$ ,  $X_4$  and  $X_5$  are amino acids as defined in any one of Claims 1 to 7.
10. A polypeptide according to Claim 8 or 9 wherein the albumin secretion pre sequence or variant thereof is a human albumin secretion pre sequence or a variant thereof.
11. A polypeptide according to Claim 10 comprising the secretion pre sequence MKWVFIVSILFLFSSAYS.
12. A polypeptide according to any one of the preceding claims wherein the leader sequence comprises a secretion pro sequence.
13. A polypeptide according to Claim 12 wherein the albumin secretion pre sequence or variant thereof is fused by a peptide bond at its C-terminal end to the N-terminal amino acid of a secretion pro sequence, or variant thereof, thereby to form a pre-pro sequence.

14. A polypeptide according to Claim 12 or 13 wherein the secretion pro sequence is an albumin secretion pro sequence or variant thereof.

15. A polypeptide according to Claim 14 wherein the albumin secretion pro sequence is human serum albumin secretion pro sequence or variant thereof.

16. A polypeptide according to Claim 14 or 15 wherein the secretion pro sequence motif is the yeast MF $\alpha$ -1 secretion pro sequence or variant thereof.

17. A polypeptide according to Claim 12 comprising the sequence:

MKWVFIVSILFLFSSAYSRY<sup>1</sup>Y<sup>2</sup>Y<sup>3</sup>Y<sup>4</sup>Y<sup>5</sup>

15

wherein Y<sup>1</sup> is Gly or Ser, Y<sup>2</sup> is Val or Leu, Y<sup>3</sup> is Phe or Asp, Y<sup>4</sup> is Arg or Lys and Y<sup>5</sup> is Arg or Lys, or variants thereof.

18. A polypeptide according to Claim 17 wherein Y<sup>1</sup> is Gly, Y<sup>2</sup> is Val and Y<sup>3</sup> is Phe; or Y<sup>1</sup> is Ser, Y<sup>2</sup> is Leu and Y<sup>3</sup> is Asp.

20

19. A polypeptide according to Claim 17 or 18 wherein Y<sup>4</sup> is Arg and Y<sup>5</sup> is Arg; Y<sup>4</sup> is Lys and Y<sup>5</sup> is Arg; Y<sup>4</sup> is Lys and Y is Lys; or Y<sup>4</sup> is Arg and Y<sup>5</sup> is Lys.

25

20. A polypeptide according to any one of claims 1 to 7 wherein at least part of said motif is present in the secretion pre-sequence.

21. A polypeptide according to any one of the preceding claims wherein the sequence of the desired protein is fused at its N-terminal end to the C-terminal amino acid of the leader sequence.
- 5 22. A polypeptide according to any one of the preceding claims where the desired protein is albumin or a variant, fragment or fusion thereof.
- 23 A polypeptide according to Claim 22 wherein the albumin is human albumin.
- 10 24. A polypeptide according to any one of Claims 1 to 21 wherein the mature polypeptide is transferrin or a variant, fragment or fusion thereof.
25. A polypeptide according to Claim 24 wherein the transferrin is
- 15 human transferrin.
26. An isolated polynucleotide comprising a sequence that encodes the motif defined by any preceding claim.
- 20 27. A polynucleotide according to Claim 26 comprising the sequence of SEQ ID No. 15.
28. A polynucleotide according to Claim 26 comprising the sequence of SEQ ID No. 16.
- 25 29. A polynucleotide according to Claim 26 comprising the sequence of SEQ ID No. 17.
30. A polynucleotide according to Claim 26 comprising the sequence of
- 30 SEQ ID No. 18.

31. A polynucleotide according to Claim 26 comprising the sequence of SEQ ID No. 34.

5 32. A polynucleotide according to Claim 30 or 31 comprising the sequence of SEQ ID No. 24.

33. A polynucleotide according to Claim 32 comprising the sequence of SEQ ID No. 25 or a variant thereof, which variant has the leader sequence  
10 of SEQ ID No.24 and encodes a variant or fragment of the albumin encoded by SEQ ID No.25.

34. A polynucleotide according to Claim 30 or 31 comprising the sequence of SEQ ID No. 27.

15

35. A polynucleotide according to Claim 34 comprising the sequence of SEQ ID No. 21 or a variant thereof, which variant has the leader sequence of SEQ ID No.27 and encodes a variant or fragment of the albumin encoded by SEQ ID No.21.

20

36. A polynucleotide comprising the sequence of SEQ ID No. 21 or fragment thereof.

37. A polynucleotide according to any one of Claims 33, 35 or 36  
25 wherein the polynucleotide comprises a DNA sequence being a contiguous or non-contiguous fusion of a DNA sequence encoding a heterologous protein with either the DNA sequence SEQ ID No. 25 or the DNA sequence SEQ ID No. 21.

38. A polynucleotide which is the complementary strand of a polynucleotide according to any one of claims 26 to 37.

39. A polynucleotide according to any one of Claims 26 to 38  
5 comprising an operably linked transcription regulatory region.

40. A polynucleotide according to Claim 39 wherein the transcription regulatory region comprises a transcription promoter.

10 41. A self-replicable polynucleotide sequence comprising a polynucleotide according any one of Claims 26 to 40.

42. A cell comprising a polynucleotide according to any one of Claims 26 to 41.

15

43. A cell according to Claim 42 which is a eukaryotic cell.

44. A cell according to Claim 43 which is a fungal cell.

20 45. A cell according to Claim 44 which is an *Aspergillus* cell

46. A cell according to Claim 44 which is a yeast cell.

25 47. A cell according to Claim 46 which is a *Saccharomyces*, *Kluyveromyces*, *Schizosaccharomyces* or *Pichia* cell.

48. A cell culture comprising a cell according to any one of Claims 42 to 47 and culture medium.

49. A cell culture according to Claim 48 wherein the medium contains a mature desired protein as a result of the production of a polypeptide as defined in any one of Claims 1 to 22.

5 50. A process for producing a mature desired protein, comprising (1) culturing a cell according to any one of Claims 42 to 47 in a culture medium wherein the cell, as a result of the production of a polypeptide as defined in any one of Claims 1 to 25, secretes a mature desired protein into the culture medium, and (2) separating the culture medium, containing the secreted  
10 mature protein, from the cell.

51. A process according to Claim 50 additionally comprising the step of separating the mature desired protein from the medium and optionally further purifying the mature desired protein.

15

52. A process according to Claim 51 additionally comprising the step of formulating the thus separated and/or purified mature desired protein with a therapeutically acceptable carrier or diluent thereby to produce a therapeutic product suitable for administration to a human or an animal.
